Biomechanics Of The Lumbar Spine

Biomechanics of the lumbar spine and sacrum (L4-L5 L5-S1) The 3 movements in the spine are flexion, extension, rotation and lateral flexion. These movements occur as a combination of rotation and translation in the following 3 planes of motion: sagittal, coronal and horizontal [3] .

Zygapophyseal, or facet, joints are complicated biomechanical structures in the spine, with a complex three-dimensional (3D) anatomy, variable mechanical functions in different spinal movements, and effects on the overall spine mechanical behavior. The 3D morphology of the facet joint is linked to its biomechanical function.

Biomechanics of the Lumbar Facet Joint

The biomechanics of the lumbar spine are related to the functional anatomy. The disparate functional mechanical requirements of the spine, support, mobility, housing, protection and control are reviewed. Typical forces one applies to the spine in activities of daily living as well as in mechanical overloads are discussed.

They permit simple gliding movements. The movement of the lumbar spine is largely confined to flexion and extension with a minor degree of rotation. The region between the superior articular process and the lamina is the pars interarticularis.

Anatomy and biomechanics of lumbar spine

the spine can be considered as a modified elastic rod because of the flexibility of the spinal column, the shock-absorbing behavior of the discs and vertebrae, the stabilizing function of the longitudinal ligaments, and the elasticity of the _____. the two curvatures of the spine in the sagittal plane—kyphosis and lordosis—also contribute to the spring-like capacity of the spine an allow ...

Spine Biomechanics The importance of the spine you ask? The spine runs from the base of the skull to the pelvis and serves as a pillar to support the body's weight and protect the spinal cord. As the back bone of the human body, damage to the spine such as...

Biomechanics, the application of mechanical principles to living organisms, helps us to understand how all the bony and soft spinal components contribute individually and together to ensure spinal stability, and how traumas, tumours and degenerative disorders exert destabilizing effects.

Vertebrae in the cervical, thoracic and lumbar sections of the spine are separated by a structure called the "intervertebral disc". This disc forms part of the joint that connects the "bodies" of two vertebrae. This joint allows very little movement between two vertebrae.

The L3 dermatome is an area of skin that receives sensations through the L3 spinal nerve and includes the front part of the thigh and inner part of the leg. The L3 myotome is a group of muscles controlled by the L3 spinal nerve and includes parts of specific muscles in the hip, thigh, and leg. The L3-L4 motion segment provides a bony enclosure to protect the cauda equina and other delicate structures.

Alterations in the lumbar lordosis in lifting resulted in significant changes in the muscle forces and internal spinal loads. Spinal shear forces at different segmental levels were influenced by changes in both the disc inclinations and extensor muscle lines of action as the posture altered.

The mechanical properties of discs are important because human lumbar IVDs are often physically disrupted (Vernon-Roberts et al., 1997), which may give rise to degenerative changes (Adams and Dolan, 2012, Adams and Roughley, 2006, Ferguson and Steffen, 2003) and to chronic back pain (Cheung et al., 2009, de Schepper et al., 2010).
